Parallel Processing Mary E. Mace, 2012-12-06 This project had its beginnings in the Fall of 1980 At that time Robert Wagner suggested that I investigate compiler optimization of data organization suitable for use in a parallel or vector machine environment We developed a scheme in which the compiler having knowledge of the machine's access patterns does a global analysis of a program's operations and automatically determines optimum organization for the data For example for certain architectures and certain operations large improvements in performance can be attained by storing a matrix in row major order However a subsequent operation may require the matrix in column major order A determination must be made whether or not it is the best solution globally to store the matrix in row order column order or even have two copies of it each organized differently We have developed two algorithms for making this determination The technique shows promise in a vector machine environment particularly if memory interleaving is used Supercomputers such as the Cray the CDC Cyber 205 the IBM 3090 as well as superminis such as the Convex are possible environments for implementation
